1 Introduction

Multi-Target Multi-Camera Tracking (MTMCT) is an essential field of research in computer vision, with significant applications ranging from video surveillance and traffic monitoring to sports analysis and crowd management. By simultaneously tracking multiple objects across various camera views, MTMCT systems aim to provide a comprehensive understanding of the scene dynamics and interactions.

The advent of deep learning and other advanced algorithms has revolutionized the field of MTMCT, especially in the last years, enabling faster, more accurate and reliable tracking in complex environments. In particular, online and real-time tracking methods have emerged as a critical area of focus, given their potential to provide timely and actionable insights in various real-world applications.

Even though Single-Target Single-Camera Tracking (ST-SCT) as well as Multi-Target Single-Camera Tracking (MT-SCT) has been extensively studied, MTMCT is still a relatively new and challenging, but also promising area of research. The complexity of MTMCT is significantly higher than ST-SCT and MT-SCT, due to the need to simultaneously track multiple objects across multiple cameras.

Single-Target Multi-Camera (ST-MCT) is a insignificant field of research, because if the use-case requires multiple cameras, it is almost always necessary to track multiple targets. Therefore, this project will not cover the special case of ST-MCT.

This research project aims to provide a comprehensive review of the state-of-the-art in MTMCT, with a special focus on online and real-time tracking methods. Latest trends, technologies, and challenges in this field are explored, drawing insights from recent research papers and studies. This review highlights the significant advancements made in MTMCT and identifies the gaps and opportunities for future research.

The rest of this project is structured as follows. Chapter 2 provides an overview of the key challenges and issues in MTMCT, along with a discussion of the datasets, metrics, and components of an MTMCT system. Furthermore it explains the basic concepts of object detection and tracking. Chapter 3 presents a detailed review of the literature on MTMCT, with the main focus on online and real-time tracking methods with static cameras, but also covering other approaches like offline tracking. Chapter 6 compares and contrasts the different methods reviewed in the previous sections, identifies the gaps and limitations in current research, and suggests areas for future research. While considering the ethical and privacy concerns related to MTMCT, it also discusses the need for regulations and guidelines. Finally, Chapter 7 concludes the project with a

summary of the key findings and insights, along with stating the future directions and challenges for research in this area.

1.1 Definition of MTMCT

MTMCT is an integration of object detection and tracking methodologies to simultaneously track multiple predefined objects of interest across various camera views. The objective of MTMCT is to maintain a coherent understanding of the identities (IDs) of the objects and trajectories as they move through the fields of view of different cameras. The objects of interest are often people and vehicles, but in theory can be any moving object. The camera setup differs from one application to another, but typically consists of multiple cameras with either overlapping, non-overlapping, or partially overlapping fields of view. The cameras may be static or moving, and may be placed at different heights and angles. The cameras may also have differing technical specifications like resolution, frame rate, and field of view (FOV).

1.2 Importance of MTMCT

MTMCT plays a crucial role in various real-world applications. In video surveillance, it is used to monitor and analyze the movement of individuals or vehicles across different cameras, which can be vital for security and forensic analysis. In sports analysis, MTMCT can provide valuable insights by tracking the movement and interaction of players across different camera angles. In traffic monitoring, MTMCT can help manage traffic flow and detect incidents by tracking vehicles as they move through different camera views.

Furthermore, the need for online and real-time tracking in these applications is imperative. Real-time processing of data streams from multiple cameras and providing instantaneous tracking results are essential to make timely and actionable insights, which is particularly relevant in scenarios like accident prevention, control of traffic flow, crime detection, and real-time sports analysis.

1.3 Objective of Research Project

First, the basics concepts of SCT are explained to provide a foundation for understanding MTMCT. The primary objective of this project is to provide a comprehensive overview of proposed methods and technologies for MTMCT and review the current state-of-the-art in MTMCT, with a special focus on online and real-time tracking methods. Through an extensive literature review, the aim is to explore the latest trends, technologies, and challenges faced in this field, and provide insights drawn

from recent research papers and studies. By highlighting the significant advancements made in MTMCT, the intend is to identify the gaps in current research and outline potential avenues for future exploration, while keeping in mind the ethical and privacy concerns related to MTMCT.

1.4 Related Work

The doctoral thesis of Tian [1, Chapter 5], published in 2019, revolves around the topic of tracking multiple objects and gives a state-of-the-art overview of this field. It does not cover the topic of multi-camera tracking. However, it provides a mathematical insight into the topic of tracking multiple objects.

The most recent and comprehensive review of MTMCT was published in 2023 by Amosa, Sebastian, Izhar, *et al.* [2]. It provides a detailed overview of the state-of-the-art in MTMCT, covering the latest trends, technologies, and challenges in this field. However, the mentioned review gives a broader overview and does not focus on online and real-time tracking methods, which is the main focus of this project. Futhermore, this research project aims to provide an easier introduction to the field of MTMCT by first explaining the basics before diving into the details of the latest research.

2 Background

This chapter provides an overview of the basic concepts of object detection and tracking and the steps of an Multi-Target Multi-Camera Tracking (MTMCT) system, along with a discussion of its key challenges and issues. Also the foundational building blocks of MTMCT are introduced, namely Single-Target Single-Camera Tracking (ST-SCT) and Multi-Target Single-Camera Tracking (MT-SCT). Furthermore it explains the datasets and metrics used to evaluate MTMCT systems.

2.1 Steps of an MTMCT System

An MTMCT system typically consists of the following steps: detection, feature extraction, data association, and tracking. Only the basic and fundamental concepts are explained in this section, more advanced and recent methods, mostly revolving around deep learning, will be discussed in chapter 3.

2.1.1 Detection

Detection refers to the process of identifying objects of interest within video frames. This is typically done using a variety of techniques, ranging from traditional image processing methods to deep learning models. The objective of the detection step is to locate and classify objects in the frame, providing a basis for subsequent steps in the MTMCT process.

2.1.2 Feature Extraction

Feature extraction involves extracting relevant information from detected objects to facilitate tracking. This could include low-level features like color, shape and texture as well as high-level features like object parts and their spatial relationships, speed, and direction of movement. The features extracted from objects are used to identify and distinguish them from other objects in the scene.

2.1.3 Data Association

Data association is the process of associating detected objects across different frames and camera views. This step is crucial in maintaining the IDs of objects as they move through the scene or even leaving and re-entering the scene, which is called re-identification (re-ID).

2.1.4 Tracking

Tracking refers to the step of maintaining the trajectory of detected objects over time. This involves predicting the future location of an object based on its past movements and updating its trajectory as new observations, so the next frame of a video, become available.

2.2 Fundamental Concepts

This section briefly describes the preliminary concepts of MTMCT, which are essential to follow the progression from basic object tracking methods to advanced MTMCT techniques.

2.2.1 Single-Target Single-Camera Tracking (ST-SCT)

ST-SCT is the simplest form of object tracking and involves tracking a single target in the field of view of a single camera. The primary goal of ST-SCT is to maintain the identity (ID) and trajectory of the target as it moves through the view of the camera.

2.2.2 Multi-Target Single-Camera Tracking (MT-SCT)

MT-SCT builds upon the principles of ST-SCT but introduces the added complexity of dealing with multiple targets in a view of a single-camera. It aims to track multiple objects simultaneously while maintaining the ID of each target and avoiding ID switches. This requires sophisticated algorithms that can handle occlusions, interactions between targets, and other challenges that especially arise in crowded scenes.

The progression from ST-SCT to MT-SCT, and ultimately to MTMCT, reflects the increasing complexity and capability of tracking systems to handle more complex scenarios. This evolution is possible, due to advances in computer vision and machine learning, which provide the tools necessary to tackle the challenges associated with tracking multiple targets across multiple camera views.

2.3 Challenges and Issues

The process of tracking multiple objects across various camera views requires careful consideration of various factors that can significantly affect the performance and accuracy of the tracking system. Some of the main challenges and issues faced in MTMCT are discussed in the following sections.

2.3.1 Occlusion

Occlusion occurs when an object is partially or completely blocked from view, making it difficult to accurately track its position and identity. This can happen when objects overlap with each other or are obstructed by other elements in the scene, such as buildings or trees. Occlusion is a common challenge in crowded environments, such as public spaces and sporting events, where multiple objects are often in close proximity to each other.

2.3.2 Varying Lighting Conditions

Lighting conditions can have a significant impact on the performance of an MTMCT system. Variations in lighting, such as changes in natural light throughout the day or artificial lighting when a tracked object enters a building, can affect the appearance of objects and make it challenging to maintain consistent tracking. The presence of shadows and reflections can also complicate the tracking process.

2.3.3 Camera Specifications

The specifications of the cameras used in an MTMCT system can have a significant impact on its performance. When multiple cameras are used, they may have different:

- **Resolution:** The number of pixels in the image
- **Frame rate:** The number of frames captured per second
- **Field of view (FOV):** The area captured by the camera
- **Angle:** The angle from which the camera captures the scene

This can make it challenging to maintain consistent tracking across different camera views, especially when objects move from one camera to another. Objects may appear differently when viewed from different cameras, and their size and shape can be distorted. Achieving accurate tracking requires the system to account for these variations and correctly align objects across different camera views.

2.4 Datasets

Datasets are a fundamental aspect of MTMCT research, they are the resource for the training, evaluation, and comparison of various tracking methods. A diverse array of datasets exists to fulfil requirements of MTMCT research, each offering unique challenges and scenarios.

Commonly utilized datasets to train object detectors are:

- **Microsoft COCO (Common Objects in Context):** Comprehensive dataset utilized for object detection, segmentation, and captioning. COCO comprises a diverse range of objects [3].
- **ImageNet:** Vast dataset employed for image classification and object detection. Object detectors trained on ImageNet are able to recognize an broad range of objects [4].

Beside these datasets, there are several datasets specifically designed for MTMCT research. These datasets are discussed in subsection 3.2.3.

2.5 Metrics and Evaluation

Evaluating the performance of a MTMCT system is critical to understand its effectiveness and reliability. Beside well known metrics like accuracy, precision and recall, there are several metrics specifically designed for multi-target and multi-camera systems. These metrics are discussed in the this section.

2.5.1 MOTP and MOTA

The Multiple Object Tracking Precision (MOTP) and Multiple Object Tracking Accuracy (MOTA) are two standard metrics used for evaluating multi-target tracking systems. MOTP measures the accuracy of the object localization, while MOTA combines three types of errors into a single metric to provide a comprehensive evaluation of the tracking performance. Both of these metrics were introduced by Bernardin and Stiefelhagen [5] in 2008.

$$\text{MOTP} = \frac{\sum_{i,t} d_t^i}{\sum_t c_t} \quad [5, \text{Eq. 1}] \quad (2.1)$$

Equation 2.1 provides a measure of the average error in estimated positions of the tracked objects. In this equation, d_t^i represents the distance between the predicted position and the ground truth position of object i at frame t , and c_t is the number of correctly matched objects (the true positives) in frame t . The distances for all

matched objects across all frames is divided by the total number of matched objects across all frames. MOTP ranges from 0 to 1, a lower MOTP value indicates higher precision in the object localization.

$$\text{MOTA} = 1 - \frac{\sum_t (m_t + fp_t + mme_t)}{\sum_t g_t} \quad [5, \text{Eq. 2}] \quad (2.2)$$

Equation 2.2 combines three types of errors to give a single performance measure. In this equation, m_t is the number of misses (true objects not detected), fp_t is the number of false positives (spurious object detections), mme_t is the number of mismatch errors (identity switches) and g_t is the total number of true objects present in frame t . The MOTA score is 1 minus the sum of all errors divided by the total number of true objects across all frames. MOTA ranges from $-\infty$ to 1, a higher MOTA value indicates better tracking accuracy.

2.5.2 IDF1

The IDF1 score is another important metric for evaluating MTMCT systems. It represents the harmonic mean of the identification precision and recall, providing a balanced measure that accounts for both the ratio of correctly identified detections and the average number of ground-truth and computed detections. This metric was introduced by Ristani, Solera, Zou, *et al.* in their widely referenced paper “Performance Measures and a Data Set for Multi-Target, Multi-Camera Tracking” [6].

$$\text{IDF}_1 = \frac{2 \times \text{IDTP}}{2 \times \text{IDTP} + \text{IDFP} + \text{IDFN}} \quad [6, \text{Eq. 11}] \quad (2.3)$$

In equation 2.3:

- **IDTP (Identification True Positives)**: Represents the number of detections that were correctly identified.
- **IDFP (Identification False Positives)**: Denotes the number of detections that were wrongly identified (misidentifications).
- **IDFN (Identification False Negatives)**: Indicates the number of actual detections that were missed or not identified.

The IDF1 metric essentially captures the identification precision and recall in multi-object tracking scenarios. The higher the IDF1 score, the better the performance of the tracker in maintaining consistent identities.

2.5.3 MT and ML

The Mostly Tracked (MT) and Mostly Lost (ML) are used to assess the effectiveness of a tracking system in maintaining consistent trajectories for the objects being tracked. The metrics published by Wu and Nevatia [7] in 2006 are commonly used in the MOTChallenge benchmarks to evaluate the performance of tracking systems.

MT measures the proportion of ground truth trajectories that are covered by the tracker for at least 80% of their respective lifetimes, indicating the ability of the system to consistently track objects over time. On the other hand, ML measures the proportion of ground truth trajectories that are covered by the tracker for less than 20% of their respective lifetimes, reflecting the inability of the system to maintain consistent object tracking.

Figure 2.1: MT and ML [7, Fig. 5]

Figure 2.1 illustrates various scenarios encountered in multi-target tracking evaluations:

- **Ground Truth Trajectory (Blue):** Represents the actual path or movement of an object in the scene.
- **Result Trajectory (Red):** Represents the predicted path of an object by the tracking system.
- **False Alarm:** Points where the tracking system detects an object when there is no one present in the ground truth.
- **ID Switch:** An instance where the tracking ID assigned to an object changes erroneously during tracking.
- **Trajectory Fragment:** A segment of the result trajectory that is shorter than the ground truth, indicating a break or interruption in tracking.
- **Mostly Tracked:** Scenarios where the result trajectory closely follows the ground truth trajectory for the majority of the path of the object ($\geq 80\%$)
- **Mostly Lost:** Scenarios where the result trajectory only briefly aligns or intersects with the ground truth trajectory, indicating the object was not effectively tracked for most of its path ($\leq 20\%$).

3 Literature Review

This chapter reviews the literature on Multi-Target Multi-Camera Tracking (MTMCT) and discusses the trends and advancements as well as the milestones in this field. It will only focus on the latest and state-of-the-art methods and technologies and will not cover the whole history of MTMCT including the early methods and algorithms.

3.1 The Beginnings

Back in 1999 and 2001 Cai and Aggarwal [8] and Chang and Gong [9] conducted research in the area of tracking people in an multi-camera system. Also in 2001, Khan, Javed, and Shah [10] proposed a method for tracking people and vehicles with uncalibrated cameras. The system is able to discover spatial relationships between the FOVs of the three cameras used. All three works rely on Bayesian classification and networks.

The methods even demonstrated the feasibility of tracking people in real-time, but are in general very limited in their capabilities. For example the work of Chang and Gong is limited to people in upright pose. The algorithm proposed by Cai and Aggarwal lacks robustness compared to the single-camera tracking and Khan, Javed, and Shah approach does not calibrate the cameras correctly and is highly susceptible to errors caused by occlusion. But since then the field of tracking in multi-camera systems has evolved significantly in the past two decades.

3.2 Milestones

This section highlights significant milestones that have shaped the MTMCT research domain, focusing on the three critical areas: object detection, data association, and datasets and benchmarks.

3.2.1 Object Detection

The foundation for modern object detection methods was laid in 1998 by Lecun, Bottou, Bengio, *et al.* with the development of Convolutional Neural Networks (CNNs), which are deep learning models specifically designed to process images [11]. The advent

of deep learning in the past quarter-century has led to a significant improvement in object detection performance.

With the introduction of R-CNN in 2014, Girshick, Donahue, Darrell, *et al.* [12] demonstrated that deep learning can be used for object detection. The architecture follows a two-stage process: first, it proposes regions of interest using a selective search and then classifies these regions using CNN features. Due to R-CNN proposing regions of interest independently, it was computationally intensive. Just one year later improvements were made with Fast R-CNN [13], addressed the inefficiencies of its predecessor by introducing a mechanism to share convolutional computations across region proposals and incorporating a Region of Interest (RoI) pooling layer to extract a fixed-size feature vector from the feature map for each proposal. In 2017 Ren, He, Girshick, *et al.* proposed Faster R-CNN [14], which integrated a Region Proposal Network (RPN) into the architecture, allowing for the generation of region proposals almost cost-free by sharing the convolutional features with the downstream detection network. This end-to-end trainable model marked a significant leap in efficiency and set a new standard for object detection tasks.

Following the success of R-CNN and its successors, the object detection landscape was further revolutionized by the introduction of You-Only-Look-Once (YOLO) [15] and Single Shot MultiBox Detector (SSD) [16], which are designed to be even more efficient and suitable for real-time applications.

The YOLO framework, presented by Redmon, Divvala, Girshick, *et al.* in 2015, revolutionized real-time object detection by predicting bounding boxes and class probabilities directly from full images in just one evaluation. YOLO processes the entire image in a single forward pass through the network, divides the image into a grid, and predicts bounding boxes and probabilities for each grid cell. The strength of YOLO lies in its speed, making it highly suitable for applications where real-time detection is crucial. Even though the original author has stopped working on YOLO, due to ethical concerns, it is still being improved continuously. The latest official version, YOLOv4, was released in 2020 by Bochkovskiy, Wang, and Liao [17].

Liu, Anguelov, Erhan, *et al.* proposed SSD in 2015, another influential single-shot object detector that balances the trade-off between speed and accuracy. Unlike YOLO, SSD operates on multiple feature maps at different resolutions to effectively handle objects of various sizes. The architecture applies a set of convolutional filters to these feature maps to predict both the bounding box offsets and the class probabilities for a fixed set of default bounding boxes, which are distributed over the image. Detecting and tracking objects across different scales and perspectives makes SSD particularly suitable for MTMCT applications.

Table 3.1 compares the mentioned prominent object detection models used in MTMCT:

- **Speed:** Refers to the time it takes for the detector to process a single frame, usually measured in frames per second (FPS). High speed is crucial for real-time

Table 3.1: Overview Object Detectors

Model	Speed	Accuracy	Computational Requirements
YOLO [15]	Very High	Moderate	Low
Faster R-CNN [14]	Moderate	High	High
SSD [16]	High	High	Moderate

tracking applications, where it is necessary to process video feeds live or near-live.

- **Accuracy:** Measures the ability to correctly identify and locate objects. It is usually quantified by precision and recall rates, or the average precision (AP) over a dataset.
- **Computational Requirements:** Refers to the resources needed to run the detector, typically measured in terms of the number of floating-point operations (FLOPs) or the memory and processing power required. Efficient use of computational resources is essential for deploying MTMCT systems on hardware with limited capabilities.

3.2.2 Data Association

Traditional approaches to data association relied heavily on probabilistic methods such as Multiple Hypothesis Tracking (MHT) [18] and Bayesian frameworks [19]. Many methods are based on the Hungarian algorithm [20] and the Kalman filter [21], which were already proposed in the 1960s by Harold Kuhn and Rudolf Kalman respectively. Furthermore fundamental feature extraction methods are Histogram of Oriented Gradients (HOG) [24] and Scale-Invariant Feature Transform (SIFT) [25].

The data association problem is tackled by three different approaches:

- **Graph Optimization:** [22]
- **Neural Networks (end-to-end):** [26]
- **Siamese Networks:** !!!
- **Re-ID:** [23]

3.2.3 Datasets and Challenges

Besides the datasets mentioned in section 2.4, which are used for object detection in general, there are also datasets which are more tailored towards MTMCT. Typically revolves around tracking specific object classes, predominantly people and vehicles. Datasets, which fits these requirements are listed in table 3.2.

Table 3.2: Overview of Datasets

Dataset	Environment	Num. of Scenarios	Num. of Cameras (Overlap)	FPS	IDs	Year	Class
MOT16 [27]	Outdoor	14	1	25-30	!!!	2016	Person, Vehicle
DukeMTMC [6]	Outdoor	1	8 (✓)	60	2834	2016	Person
WILDTRACK [28]	Outdoor	1	7 (✓)	60	313	2018	Person
MSMT17 [29]	Mixed	12	15 (✓)	15	4101	2018	Person
CityFlowV1 [30]	Outdoor	5	40 (✓)	10	666	2019	Vehicle
MOT20 [31]	Outdoor	8	1	25	!!!	2020	Person, Vehicle
CityFlowV2 [30]	Outdoor	6	46 (✓)	10	880	2021	Vehicle
MMPTRACK [32]	Indoor	5	23 (✓)	15	!!!	2023	Person
MEVID [33]	Mixed	17	33 (✓)	!!!	158	2023	Person

Table 3.2 provides a summary of various datasets that have significantly contributed to the MTMCT research domain. Each dataset is categorized based on several distinct criteria to reflect its unique characteristics and relevance:

- **Environment:** Setting of data collection, from controlled indoor environments to dynamic outdoor locations.
- **Num. of Scenarios:** Details the number of distinct scenarios or situations represented in the dataset.
- **Num. of Cameras (Overlap):** Represents the number of cameras involved and indicates if there is an overlap in their views.
- **FPS:** Specifies the frame rate of the dataset, important for real-time processing considerations.
- **IDs:** Enumerates the unique identities present, which can provide a measure of the complexity of the dataset.
- **Year:** States the year of the release, representing the recentness of the dataset.
- **Class:** Identifies the subjects annotated, such as persons or vehicles.

Each dataset listed plays a role in the following sections, the reviewed literature is often evaluated on one or more of these datasets. The datasets are also used to train and test the tracking methods.

In recent years, challenges have been established to encourage research in object detection and tracking, although they have mostly centered on ST-SCT and MT-SCT. Nevertheless, these challenges remain relevant to MTMCT research. The most recent representatives of the primary challenges are:

- **MOT20 Challenge:** Benchmark, which includes crowded environments and variable lighting conditions. Moreover, it provides ground truth data to facilitate evaluation. The MOT datasets are released in conjunction with the MOTChallenge [31].

- **2023 AICity Challenge:** Focuses on AI applications in smart cities and includes multi-object tracking for traffic surveillance and anomaly detection as one of its key components. The CityFlow datasets belong to the AICity Challenges. [34]
- **VOT2022 Challenge (Visual Object Tracking Challenge):** An annual competition that provides a standardized dataset and evaluation framework for single-object tracking. [35]
- **VOTS2023 Challenge (Visual Object Tracking and Segmentation Challenge):** An extension of the VOT Challenge that focuses on multi-object tracking. The challenge, recently published in October 2023, affirms the quickly growing interest in this field. [36]

3.3 Methods

This section reviews the methods and state-of-the-art algorithms used in MTMCT.

3.3.1 Tracking-by-Detection

The most common approach used by MTMCT systems is to first detect the objects in each frame and then data association is performed to link the detections across frames. This implementation is known as Tracking-by-Detection (TbD) and the two steps are performed separately and sequentially.

3.3.2 Graph Optimization

3.3.3 Neural Networks

3.3.4 Siamese Networks

3.3.5 Edge Computing

3.4 Strengths and Weaknesses

This section discusses the strengths and weaknesses of the reviewed methods and algorithms.

4 Online and Real-Time Tracking

4.1 Significance and Benefits

Explain the significance of online and real-time tracking in MTMCT and its benefits over offline tracking methods.

4.2 Algorithms and Technologies

Review the latest algorithms and technologies used for online and real-time tracking, such as Siamese networks, deep reinforcement learning, and edge computing.

4.3 Challenges and Limitations

Discuss the challenges specific to online and real-time tracking, such as handling large data streams and ensuring low latency.

Evaluate the performance and limitations of existing online and real-time tracking systems.

5 Other Methods

Briefly review other methods used in MTMCT, such as offline tracking, semi-supervised tracking, and unsupervised tracking. Compare and contrast these methods with online and real-time tracking. Highlight the scenarios where these methods may be more suitable or beneficial.

6 Discussion

6.1 Comparison of Methods

Compare and contrast the different methods reviewed in the previous chapters.

6.2 Gaps and Limitations

Identify the gaps and limitations in current research.

6.3 Future Research

Suggest areas for future research.

6.4 Ethical and Privacy Concerns

Discuss the ethical and privacy concerns related to MTMCT and the need for regulations and guidelines.

7 Conclusion

7.1 Summary

Summarize the main points made in your paper.

Highlight the importance of online and real-time tracking in MTMCT and its potential to revolutionize various applications.

7.2 Future Directions

Conclude by stating the future directions and challenges for research in this area.

8.1 Citations

8.1.1 General

[2]: Current Trends in MCMOT. State of the Art. A lot of basic and advanced knowledge. Good for introduction. Analyzes 30 MCT algorithms.

[1]: General description of multi-camera tracking. State of the Art, Markov Process, graph partition theory, tracking by joint constraints.

[10]: Tracking people in multiple uncalibrated cameras. Discover spatial relationships between the camera FOVs. Tested on PETS 2001.

8.1.2 Beginning

[8]: First approaches of tracking humans in multi camera network. Already done in 1999 with real-time tracking. Automatic camera switching. Bayesian classification schema.

[9]: Bayesian modality fusion to track multiple people in an indoor environment. Tries to fix already known occlusion problem.

8.1.3 Real-time

[14]: Faster R-CNN. Towards Real-Time Object Detection. Region Proposal Network (RPN). RPN is trained end-to-end. Attention mechanism. 5-17 fps on GPU. Two modules (first region proposal, second detector). Sharing convolutional features.

[37]: Toward Real-Time. Only multi-object tracking. Introduces JDE (Joint learning of detection and embedding). Very important paper (first real-time MOT system). Single-shot detector

[38]: Indoor scene, multiple top-view **fisheye** cameras. Possible to cover large space, less occlusion among objects. People detection and tracking. Calibrate cameras, real time (FPS of about 10) without GPU support.

[39]: Real-time distributed MCMOT system. City-scale scenario. Keeping communication and computing costs of each device low. Installs smart stations on the roadside and connects them to maintain communication. Decentralized Tracking. Kalman filter and hungarian algorithm. YoloX and DeepSORT.

[40]: FairMOT, one-shot tracker (anchor-free style). Tackles issue of object detection against re-ID. Re-ID often threatened as secondary task. Reasons behind failure: anchors, feature sharing, feature dimension.

[41]: Multiple non-overlapping cameras using fast-constrained dominant set clustering (FCDSC). Three-layer hierarchical approach. Orders of magnitudes faster than existing methods. Can be used in conjunction with re-id algorithms. Good graphics in paper.

8.1.4 VOT

[42]: VOT21 Challenge Results. Considers single-camera, single-target, model-free tracking. VOT-RT2021 focuses on real-time RGB tracking. Requires predicting bounding boxes. Top two trackers: TrasT_M and STARK_RT.

[35]: VOT22 Challenge Results. Considers single.camera, single-target. VOT-RT2022 focuses on real-time RGB tracking, VOT-RTs by segmentation, VOT-RTb by bounding boxes. Goes beyond previous challenges (updating datasets). Real-time tracking at 20fps. Top trackers: MS_AOT and OTrackSTB.

[36] VOTS23 Challenge Results. First year considering multiple-target tracking challenge. Explores short- and long-term at once. Only one challenge for all. Does not distinguish between these scenarios. Success is measured in IoU, tracking Quality \mathbf{Q} , Accuracy, Robustness, NRE, DRE, ADQ. Dataset with challenging situations, wide range and diverse set of objects, object which are a part of other objects. Also longer videos. 77 trackers submitted, 47 valid. Most trackers applied uniform dynamic model, utilized transformers, general segmentation network SAM. Top tracker: DMAOT built upon VOT22 winner AOT. Best segmentation-based trackers outperformed all bound.box trackers.

8.1.5 Dynamic Cameras

[43]: Tracking multiple vehicles in the front view of an onboard monocular camera. Siamese network with a spatial pyramid pooling. Markov decision process. Effective for real-time long-term tracking. Hungarian algorithm, reinforcement learning.

[44]: Single-Stage Global Association Approach. Dynamic MCMOT (moving cameras in vehicle). Solves fragment-tracking issues. Not relevant for static MCMOT.

8.1.6 Person Tracking

[45]: Integrating social grouping behavior for tracking pedestrians. Online learned conditional random field (CRF). Non-overlapping cameras.

[46]: Non-overlapping cameras. Pedestrian Tracking. Fix ID-switching issues with long-term feature extraction. OC-SORT + feature extraction.

[47]: Soccer Players. Raw detection heat maps. Google Research Football Environment. Multi camera, multi targets. Cameras have fixed positions. Do not use bounding boxes, instead raw input with heat maps. Graph Neural Network. No visual cues, such as jersey numbers. Player movement trajectories and interaction between neighborhood players.

[48]: Optical-based Pose Association (OPA). Online data association algorithm. Solve the occlusion problem. Take also human pose (see [49]) and optical flow into account, not only visual and spatial information. OpenPose, Object Keypoint Similarity, PWC-Net, Kunh-Munkras algorithm.

8.1.7 Vehicle Tracking (AI City)

[50]: Multi-camera vehicle tracking. No real-time tracking. Improve single-camera tracklets. 4th place in 2022 AI City Challenge. Track refinement module. Yolov5 pre-trained on COCO. Using GAN to generate synthetic data. Background filtering. Hierarchical clustering, zones, two rounds of clustering (tracklets separately each possible transition between cameras, akk tracks fro adjacent cameras).

[51]: Inspired [50]. First place in 2021 AI City Challenge. Yolov5 pre-trained on COCO. Most important: Introduces two step clustering (inter-zone, inter-camera clustering).

[52]: Fourth place in 2021 AI City Challenge (Track 3). Occlusion-aware tracking system. Inspired by Stadler.

[53]: Second place in 2022 AI City Challenge (Track 1). No new innovations made on first glance.

[54]: First place in 2020 AI City Challenge (Track 3). Electricity. Efficient vehicle tracking system. Aggregation loss and fast multi-target cross-camera tracking strategy. Weighted inter-class non-maximum suppression.

[55]: Graph Auto-Encoder and Self-Supervised Camera Link Model. First implementation of GAE in MTMCT. Very interesting paper. Network topology is learned automatically.

8.1.8 Re-ID, Data Association and Tracklet Matching

[56]: Unsupervised cross-dataset transfer learning for person re-id. Unsupervised multi-task dictionary learning (UMDL) model. Uses latent attributes. Asymmetric multi-task learning approach.

[57]: First time use of hierarchical clustering for person re-id. No online method (needs neighboring frames).

[58]: Online-learning-based person re-id. Fully unsupervised learning method. Systematically builds camera link model. Two-way GMM fitting. Multi-kernel adaptive segmentation. Multi-shot framework.

[59]: Orientation-driven person re-id (ODPR). Leverages the orientation cue and stable torso features to learn a discriminative representation. Also estimates camera topology. Entry/Exit zones are clustered with GMM.

[60]: Locality aware appearance metric (LAAM). Intra- and inter-camera metric for re-ID. Can be applied on top of globally learned re-ID features. Improves tracking accuracy.

[49]: State-aware Re-ID. Human pose information is adopted to infer the target state including occlusion status and orientation. State-of-the-art result on Duke-MTMCT.

[61]: Proposes Mutual Information Temporal Weight Aggregated Person Re-ID Model (MI-TWA). Person re-identification. New algorithm. Not so interesting.

[62]: Dynamic Graph Model with Link Prediction. Tackles problem of data association with a dynamic graph model. Better feature representations and able to recover from lost tracks during camera transitions. Works for person and vehicle tracking for overlapping and non-overlapping cameras. First time link prediction and dynamic graph are used together for MCMOT. Attention models.

[63]: Metadata-Aided Re-ID. Uses metadata information (car type, brand and color) for re-ID. Traffic-aware single-camera tracking. trajectory-based camera link model. Not so interesting.

[64]: Tracklet-to-Target Assignment. Solves cross-camera tracklet matching problem by TRACTA. Proposes the Restricted Non-negative Matrix Factorization (RNMF) algorithm. Estimates the number of targets in the whole network. Important paper.

8.1.9 Datasets

[6]: Largest annotated calibrated data set for MTMC (DukeMTMC).

[65]: Created MTMCT dataset in GTA V. No privacy issues. 6 cameras over 100 minutes per camera. Largest synthetic dataset for multi camera multi person tracking.

[66]: HOTA as new tracking performance measure

8.1.10 Misc

[67]: Tracking framework for multiple interacting targets both overlapping and non-overlapping cameras, raw target trajectory with group state. SVMS, homography-based voting schema, networkflow problem, K-shortest paths algorithm.

[68]: Non-overlapping multiple cameras tracking based on similarity function. Data association method. Similarity based on color appearance and camera topology. Use superpixels for extracting color features generated by Simple Linear Iterative Clustering K-means camera topology learning.

[69]: Multiple hypothesis tracking (MHT) for multi-camera tracking. Track hypothesis trees. Disjoint views. Status: tracking, searching, end-of-track. Real-time online method (15 fps). Also uses pose of person.

[70]: Mathematical multi-camera tracking approach. Pre-clustering obtained from 3D geometry projections.

[71]: Utilizes information regarding spatial and temporal consistency. Reconfigurable graph model. Two step approach: Associate all objects across cameras spatially then reconfig into a temporal graph model. Matching object across different views.

[72]: Equalized Global Graph Model-Based Approach. Improved similarity metric for single- and multiple-camera tracking. SCT and ICT in one step.

[73]: Joint person re-id and camera network topology inference. First framework which jointly solves both problems. Minimal prior knowledge about environment. Multi-shot method implemented as random-forest.

[74]: Joint learning of feature, affinity and multi-dimensional assignment (FAMNet). Online MOT. One deep-network for all three tasks. End-to-end learning.

8.2 Approaches

Single vs Multi Camera Tracking

Static vs Dynamic MCMOT

Single-Stage vs Multi-Stage Tracking

Intra camera vs Inter camera tracking

Local and Global tracklets

Cross-camera tracklet matching problem

Graph Neural Networks, Self-Attention, Transformers

Hierarchical Clustering

Gaussian Mixture Models (GMM)

Tracking by detections (Multi-shot) vs One-shot (Single-shot)

Challenges: Occlusion, perspective changes, changes in lighting, changes in appearances, unknown number of targets in the whole network, unknown number of cameras in which a certain target appears.

Common Pipeline:

- Detection
- Feature Extraction
- Single Camera Tracking
- Cross Camera Association
- Multi Camera Tracking

8.3 Die Beschics

Single Object Detection (SOD)

Multi Object Detection (MOD)

Object Re-Identification (ReID)

Single Camera Tracking (SCT)

Multi Camera Tracking (MCT)

Camera Link Model (CLM)

Trajectories and Tracklets

Fisheye vs Normal Cameras

Online vs Offline Tracking (Online: real-time and frame-by-frame, Offline: post-processing)

Local neighborhood: Single-camera tracking: Consecutive frames. Multi-camera tracking: Neighboring cameras.

Different cameras have different technical characteristics.

Appearance features vs Motion features

Datasets:

- DukeMTMC
- MOTChallenge
- AI City Challenge
- PETS
- CityFlow
